

MoCT Labs – Storyboarding

Intro – What are the Use Case Storyboards?

Use-case storyboards are used to understand and reason about the requirements of the user interface, including usability requirements. They represent a high-level understanding of the user interface, and are much faster to develop than the actual user interface. The use-case storyboards can thus be used to create and reason about several versions of the user interface before it is prototyped, designed, and implemented.

Use case storyboards represent the user-system interaction described in use case scenarios in terms of system screens. The main question answered by use case storyboards is how the interaction looks like screen by screen when system actor tries to achieve her/his goal goal.

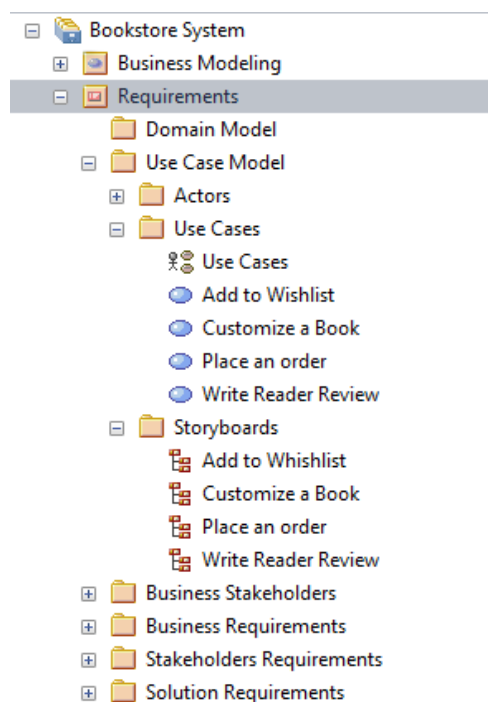

After you have storyboards prepared then you can skip to Robustness Analysis.

The storyboarding process may be done in 2 stages.

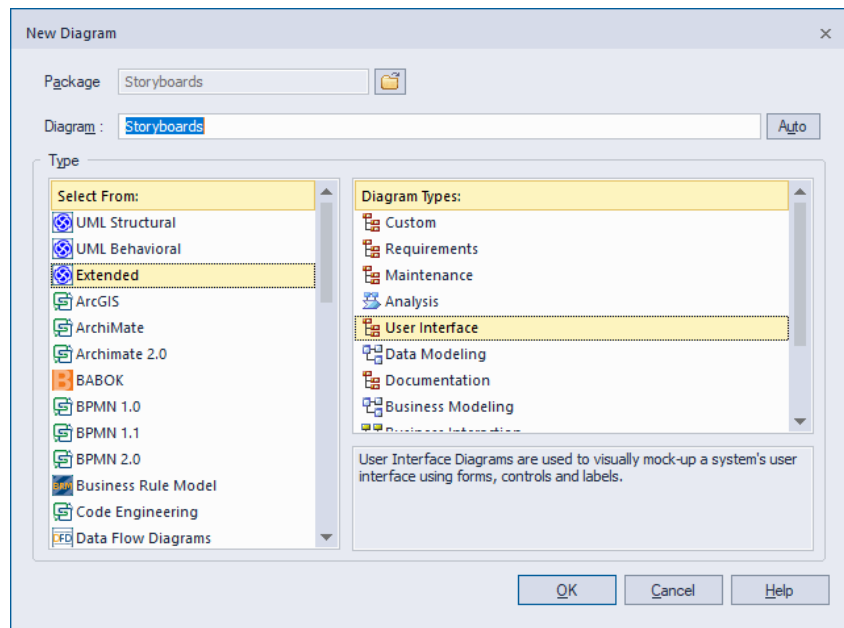

1. Happy day scenarios story boarding. Such storyboard includes high level representation how the user navigate from screen to screen during use case realization.
2. Wireframing of every screen to show what GUI elements the screen should have.
3. Elaboration of storyboards to include alternative and exception scenarios.

Project Artifacts Organization

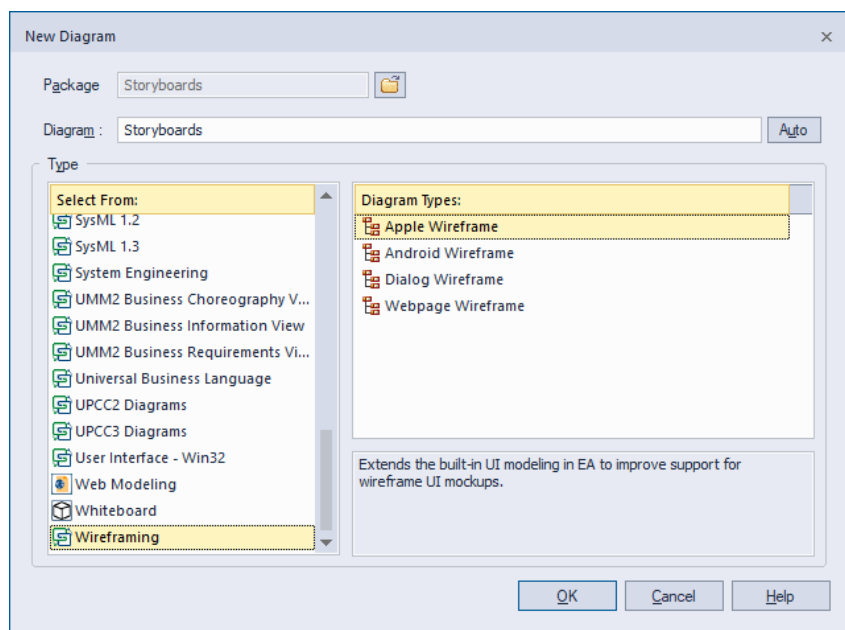

Storyboards are prepared for every use case. Therefore the name of the storyboard should be the same as the name of the use case for which storyboard is being developed. It is important to properly name every screen in storyboard. The structure of the project is presented on the figure below.

For storyboard diagram use Extended | User Interface.

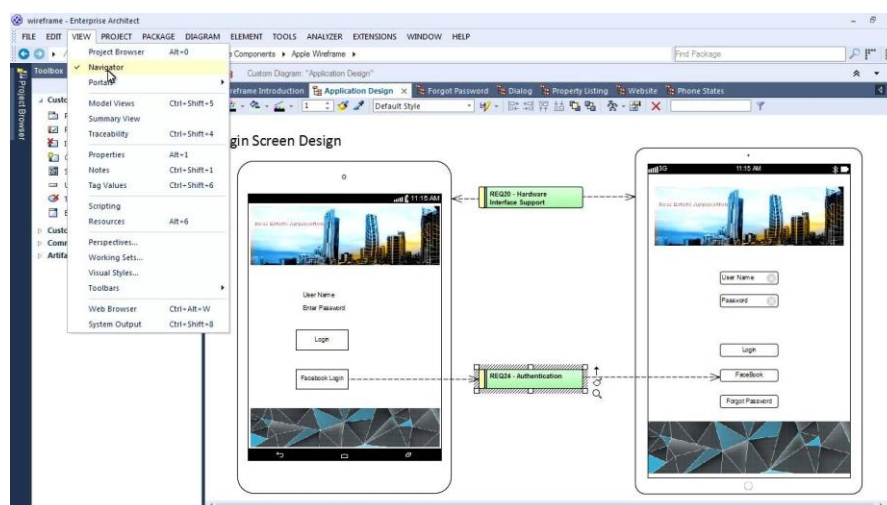

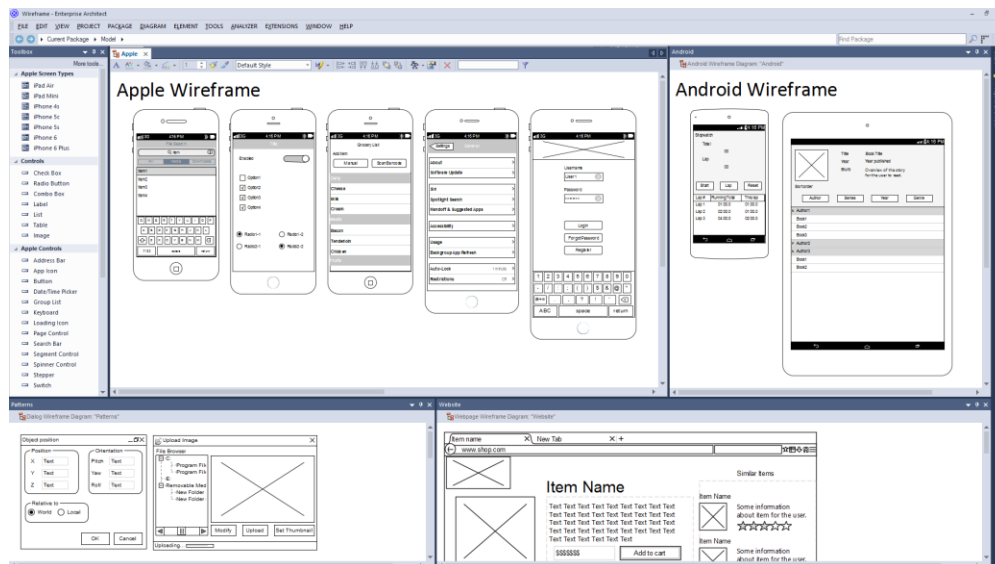

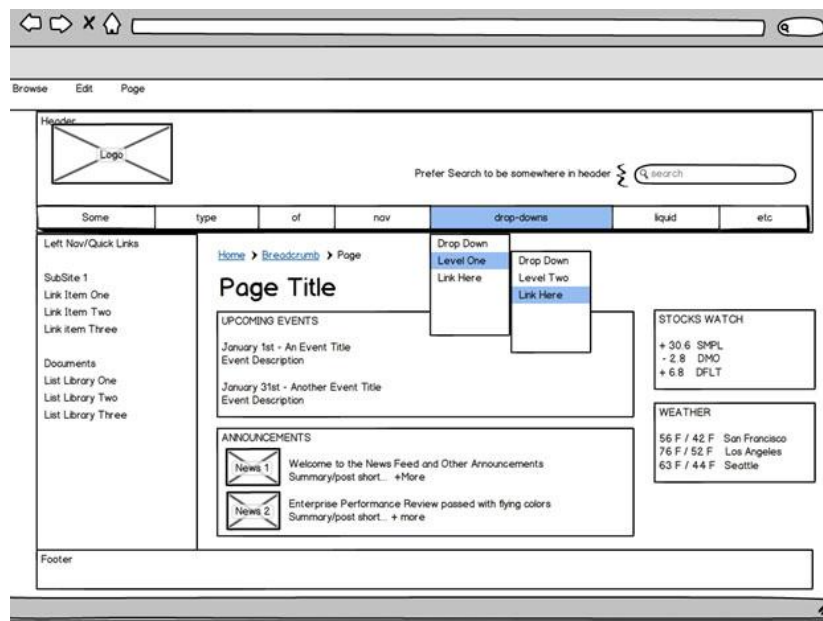

For wireframes use proper wireframe diagram depending on what device will be used by users. Wireframing | Android | Apple | Webpage | Dialog.

After you have storyboard created you should connect every screen from storyboard with wireframe diagram showing how it looks like in terms of GUI elements.

Sample Wireframes

Assignment

1. For the *Customize a Book* use case scenario presented below develop a storyboard and wireframes for screens. Connect screens with wireframes.

Use case Name: *Customize a book*

Pre-condition (Logged in user)

Customer is logged into the system.

Happy day scenario

1. Customer select Create a book option.
2. System displays two options: Search and Browse
3. Customer selects Browse option.
4. System presents e-catalog categories.
5. Customer selects the book.
6. System displays book's content.
7. Customer selects the chapter and then add option.
8. System creates new book canvas, adds selected chapter
9. and display options: new item, finish.
10. Customer selects finish option and selects file format from format options provided by system.
11. System saves the book's file in customer's library.

Post-condition (Customized book created)

Customized book file has been created and saved in the library.

2. For the use cases *Add to Wishlist* and *Write Reader Review* develop storyboards and then prepare scenarios.
